NAG Library Routine Document F08CHF (DGERQF)

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of **bold italicised** terms and other implementation-dependent details.

1 Purpose

F08CHF (DGERQF) computes an RQ factorization of a real m by n matrix A.

2 Specification

```
SUBROUTINE FO8CHF (M, N, A, LDA, TAU, WORK, LWORK, INFO)

INTEGER M, N, LDA, LWORK, INFO

REAL (KIND=nag_wp) A(LDA,*), TAU(*), WORK(max(1,LWORK))
```

The routine may be called by its LAPACK name dgeraf.

3 Description

F08CHF (DGERQF) forms the RQ factorization of an arbitrary rectangular real m by n matrix. If $m \le n$, the factorization is given by

$$A = \begin{pmatrix} 0 & R \end{pmatrix} Q,$$

where R is an m by m lower triangular matrix and Q is an n by n orthogonal matrix. If m > n the factorization is given by

$$A = RQ$$

where R is an m by n upper trapezoidal matrix and Q is again an n by n orthogonal matrix. In the case where m < n the factorization can be expressed as

$$A = \begin{pmatrix} 0 & R \end{pmatrix} \begin{pmatrix} Q_1 \\ Q_2 \end{pmatrix} = RQ_2,$$

where Q_1 consists of the first (n-m) rows of Q and Q_2 the remaining m rows.

The matrix Q is not formed explicitly, but is represented as a product of $\min(m, n)$ elementary reflectors (see the F08 Chapter Introduction for details). Routines are provided to work with Q in this representation (see Section 9).

5 Arguments

1: M – INTEGER Input

On entry: m, the number of rows of the matrix A.

Constraint: $M \ge 0$.

Mark 26 F08CHF.1

F08CHF NAG Library Manual

2: N – INTEGER Input

On entry: n, the number of columns of the matrix A.

Constraint: $N \ge 0$.

3: $A(LDA,*) - REAL (KIND=nag_wp) array$

Input/Output

Note: the second dimension of the array A must be at least max(1, N).

On entry: the m by n matrix A.

On exit: if $m \le n$, the upper triangle of the subarray A(1:m,n-m+1:n) contains the m by m upper triangular matrix R.

If $m \ge n$, the elements on and above the (m-n)th subdiagonal contain the m by n upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of $\min(m,n)$ elementary reflectors (see Section 3.3.6 in the F08 Chapter Introduction).

4: LDA – INTEGER Input

On entry: the first dimension of the array A as declared in the (sub)program from which F08CHF (DGERQF) is called.

Constraint: LDA $\geq \max(1, M)$.

5: TAU(*) - REAL (KIND=nag_wp) array

Output

Note: the dimension of the array TAU must be at least max(1, min(M, N)).

On exit: the scalar factors of the elementary reflectors.

6: WORK(max(1,LWORK)) - REAL (KIND=nag wp) array

Workspace

On exit: if INFO = 0, WORK(1) contains the minimum value of LWORK required for optimal performance.

7: LWORK – INTEGER

Input

On entry: the dimension of the array WORK as declared in the (sub)program from which F08CHF (DGERQF) is called.

If LWORK =-1, a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued.

Suggested value: for optimal performance, LWORK \geq M \times nb, where nb is the optimal **block** size.

Constraint: LWORK $\geq \max(1, M)$ or LWORK = -1.

8: INFO – INTEGER Output

On exit: INFO = 0 unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

INFO < 0

If INFO = -i, argument i had an illegal value. An explanatory message is output, and execution of the program is terminated.

F08CHF.2 Mark 26

7 Accuracy

The computed factorization is the exact factorization of a nearby matrix A + E, where

$$||E||_2 = O\epsilon ||A||_2$$

and ϵ is the *machine precision*.

8 Parallelism and Performance

F08CHF (DGERQF) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the X06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this routine. Please also consult the Users' Note for your implementation for any additional implementation-specific information.

9 Further Comments

The total number of floating-point operations is approximately $\frac{2}{3}m^2(3n-m)$ if $m \le n$, or $\frac{2}{3}n^2(3m-n)$ if m > n.

To form the orthogonal matrix Q F08CHF (DGERQF) may be followed by a call to F08CJF (DORGRQ):

```
CALL DORGRO(N,N,MIN(M,N),A,LDA,TAU,WORK,LWORK,INFO)
```

but note that the first dimension of the array A must be at least N, which may be larger than was required by F08CHF (DGERQF). When $m \le n$, it is often only the first m rows of Q that are required and they may be formed by the call:

```
CALL DORGRO (M, N, M, A, LDA, TAU, WORK, LWORK, INFO)
```

To apply Q to an arbitrary real rectangular matrix C, F08CHF (DGERQF) may be followed by a call to F08CKF (DORMRQ). For example:

forms $C = Q^{T}C$, where C is n by p.

The complex analogue of this routine is F08CVF (ZGERQF).

10 Example

This example finds the minimum norm solution to the underdetermined equations

$$Ax = b$$

where

$$A = \begin{pmatrix} -5.42 & 3.28 & -3.68 & 0.27 & 2.06 & 0.46 \\ -1.65 & -3.40 & -3.20 & -1.03 & -4.06 & -0.01 \\ -0.37 & 2.35 & 1.90 & 4.31 & -1.76 & 1.13 \\ -3.15 & -0.11 & 1.99 & -2.70 & 0.26 & 4.50 \end{pmatrix} \quad \text{and} \quad b = \begin{pmatrix} -2.87 \\ 1.63 \\ -3.52 \\ 0.45 \end{pmatrix}$$

The solution is obtained by first obtaining an RQ factorization of the matrix A.

Note that the block size (NB) of 64 assumed in this example is not realistic for such a small problem, but should be suitable for large problems.
