## **NAG Library Routine Document**

### G02HKF

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of **bold italicised** terms and other implementation-dependent details.

### 1 Purpose

G02HKF computes a robust estimate of the covariance matrix for an expected fraction of gross errors.

## 2 Specification

### 3 Description

For a set of n observations on m variables in a matrix X, a robust estimate of the covariance matrix, C, and a robust estimate of location,  $\theta$ , are given by

$$C = \tau^2 \left( A^{\mathsf{T}} A \right)^{-1},$$

where  $\tau^2$  is a correction factor and A is a lower triangular matrix found as the solution to the following equations:

$$z_i = A(x_i - \theta),$$

$$\frac{1}{n} \sum_{i=1}^{n} w(\|z_i\|_2) z_i = 0,$$

and

$$\frac{1}{n} \sum_{i=1}^{n} u(\|z_i\|_2) z_i z_i^{\mathsf{T}} - I = 0,$$

where  $x_i$  is a vector of length m containing the elements of the ith row of X,

 $z_i$  is a vector of length m,

I is the identity matrix and 0 is the zero matrix,

WK(N+M\*(M+5)/2)

and w and u are suitable functions.

G02HKF uses weight functions:

$$u(t) = \frac{a_u}{t^2}, \quad \text{if } t < a_u^2$$
 
$$u(t) = 1, \quad \text{if } a_u^2 \le t \le b_u^2$$
 
$$u(t) = \frac{b_u}{t^2}, \quad \text{if } t > b_u^2$$

and

Mark 24 G02HKF.1

G02HKF NAG Library Manual

$$w(t) = 1$$
, if  $t \le c_w$ 

$$w(t) = \frac{c_w}{t}$$
, if  $t > c_w$ 

for constants  $a_u$ ,  $b_u$  and  $c_w$ .

These functions solve a minimax problem considered by Huber (see Huber (1981)). The values of  $a_u$ ,  $b_u$  and  $c_w$  are calculated from the expected fraction of gross errors,  $\epsilon$  (see Huber (1981) and Marazzi (1987)). The expected fraction of gross errors is the estimated proportion of outliers in the sample.

In order to make the estimate asymptotically unbiased under a Normal model a correction factor,  $\tau^2$ , is calculated, (see Huber (1981) and Marazzi (1987)).

The matrix C is calculated using G02HLF. Initial estimates of  $\theta_j$ , for j = 1, 2, ..., m, are given by the median of the jth column of X and the initial value of A is based on the median absolute deviation (see Marazzi (1987)). G02HKF is based on routines in ROBETH; see Marazzi (1987).

### 5 Parameters

1: N – INTEGER Input

On entry: n, the number of observations.

Constraint: N > 1.

2: M – INTEGER Input

On entry: m, the number of columns of the matrix X, i.e., number of independent variables.

Constraint:  $1 \le M \le N$ .

3: X(LDX,M) - REAL (KIND=nag wp) array

Input

On entry: X(i, j) must contain the *i*th observation for the *j*th variable, for i = 1, 2, ..., N and j = 1, 2, ..., M.

4: LDX – INTEGER Input

On entry: the first dimension of the array X as declared in the (sub)program from which G02HKF is called.

*Constraint*: LDX  $\geq$  N.

5: EPS – REAL (KIND=nag wp)

Input

On entry:  $\epsilon$ , the expected fraction of gross errors expected in the sample.

Constraint:  $0.0 \le EPS < 1.0$ .

6:  $COV(M \times (M+1)/2) - REAL$  (KIND=nag wp) array

Output

On exit: a robust estimate of the covariance matrix, C. The upper triangular part of the matrix C is stored packed by columns.  $C_{ij}$  is returned in  $COV((j \times (j-1)/2 + i))$ ,  $i \le j$ .

7: THETA(M) – REAL (KIND=nag\_wp) array

Output

On exit: the robust estimate of the location parameters  $\theta_j$ , for j = 1, 2, ..., m.

G02HKF.2 Mark 24

#### 8: MAXIT – INTEGER

Input

On entry: the maximum number of iterations that will be used during the calculation of the covariance matrix.

Constraint: MAXIT > 0.

#### 9: NITMON – INTEGER

Input

On entry: indicates the amount of information on the iteration that is printed.

NITMON > 0

The value of A,  $\theta$  and  $\delta$  (see Section 7) will be printed at the first and every NITMON iterations.

NITMON < 0

No iteration monitoring is printed.

When printing occurs the output is directed to the current advisory message unit (see X04ABF).

#### 10: TOL – REAL (KIND=nag wp)

Input

On entry: the relative precision for the final estimates of the covariance matrix.

Constraint: TOL > 0.0.

#### 11: NIT – INTEGER

Output

On exit: the number of iterations performed.

12: 
$$WK(N + M \times (M + 5)/2) - REAL (KIND=nag_wp)$$
 array

Workspace

#### 13: IFAIL – INTEGER

Input/Output

On entry: IFAIL must be set to 0, -1 or 1. If you are unfamiliar with this parameter you should refer to Section 3.3 in the Essential Introduction for details.

For environments where it might be inappropriate to halt program execution when an error is detected, the value -1 or 1 is recommended. If the output of error messages is undesirable, then the value 1 is recommended. Otherwise, if you are not familiar with this parameter, the recommended value is 0. When the value -1 or 1 is used it is essential to test the value of IFAIL on exit.

On exit: IFAIL = 0 unless the routine detects an error or a warning has been flagged (see Section 6).

### 6 Error Indicators and Warnings

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

Errors or warnings detected by the routine:

IFAIL = 1

```
\begin{array}{llll} \text{On entry,} & N \leq 1, \\ \text{or} & M < 1, \\ \text{or} & N < M, \\ \text{or} & LDX < N, \\ \text{or} & EPS < 0.0, \\ \text{or} & EPS \geq 1.0, \\ \text{or} & TOL \leq 0.0, \\ \text{or} & MAXIT < 0. \end{array}
```

Mark 24 G02HKF.3

G02HKF NAG Library Manual

```
IFAIL = 2
```

On entry, a variable has a constant value, i.e., all elements in a column of X are identical.

#### IFAIL = 3

The iterative procedure to find C has failed to converge in MAXIT iterations.

#### IFAIL = 4

The iterative procedure to find C has become unstable. This may happen if the value of EPS is too large for the sample.

### 7 Accuracy

On successful exit the accuracy of the results is related to the value of TOL; see Section 5. At an iteration let

- (i) d1 = the maximum value of the absolute relative change in A
- (ii) d2 = the maximum absolute change in  $u(||z_i||_2)$
- (iii) d3 = the maximum absolute relative change in  $\theta_i$

and let  $\delta = \max(d1, d2, d3)$ . Then the iterative procedure is assumed to have converged when  $\delta < \text{TOL}$ .

#### **8 Further Comments**

The existence of A, and hence C, will depend upon the function u (see Marazzi (1987)); also if X is not of full rank a value of A will not be found. If the columns of X are almost linearly related, then convergence will be slow.

# 9 Example

A sample of 10 observations on three variables is read in and the robust estimate of the covariance matrix is computed assuming 10% gross errors are to be expected. The robust covariance is then printed.
